Marker genes behind each cell population, 1-month Ddx41 conditional-knockout retina

CHX10-Cre; Ddx41 fl/fl vs. littermate control, n = 3 per genotype. Every gene in the curated panels, sorted by fold change within its population. Cones, horizontal cells and retinal ganglion cells fall coherently; rod genes sit just above the library-scaling line, which is what a gain in share looks like rather than induction. Reactive gliosis is the one population whose genes move by more than two-fold on their own.
